Prostaglandins, highly active substances released by cells, are currently classified as leukotrienes and prostanoids (prostaglandins and thromboxanes). They are synthesized from a common precursor, arachidonic acid. They are involved in the physiological and pathological processes in the body, and are also used in dermatology for many purposes, such as treatment of acne, sunburn and other erythematous diseases and for the relief of pruritus. Other uses include inhibition of platelet aggregation and reduction of nasal bleeding following surgery, prevention of premature labor, treatment of glaucoma and prevention of the rejection of transplanted organs. The research on the biological effects of prostaglandins is very active and much is already known about their usefulness in dermatology. It is also possible that further progress in the field will result in the development of products which will play a significant role in dermatology.Q: Meaning of x/0 I've heard this being used in a number of people, but I'm not sure of what it means.
